BioOne sees sustainable scholarly publishing as an inherently collaborative enterprise connecting authors, nonprofit publishers, academic institutions, research libraries, and research funders in the common goal of maximizing access to critical research.

***CULICOIDES PARAENSIS* (DIPTERA: CERATOPOGONIDAE) INFESTATIONS IN CITIES OF THE ITAPOCÚ RIVER VALLEY, SOUTHERN BRAZIL¹**

Maria Luiza Felipe-Bauer² and Ulises Sebastian Sternheim³

ABSTRACT: *Culicoides paraensis* (Goeldi), a vector of the human viral disease Oropouche, is reported as a pest from five cities in the Itapocú River Valley, southern Brazil. Adults likely emerge from rotting banana plants and are common enough to cause skin problems and allergies.

KEY WORDS: Diptera, Ceratopogonidae, *Culicoides paraensis*, infestations, pest, southern Brazil

Culicoides paraensis (Goeldi, 1905) is the most important species of Ceratopogonidae with medical importance in the Neotropical Region. It is a vector to humans of the nematode *Manzonella ozzardi*, in Argentina (Shelley and Coscarón, 2002) and Oropouche (ORO) virus infections in Panama, Peru and Brazil (Tesh, 1994). Over a half million persons have been infected with ORO virus. This makes this viral disease a serious public health threat in tropical and subtropical areas of Central and South America (Pinheiro et al., 2004).

In Brazil, ORO epidemics have been reported from 1960 to 1980 in the northern state of Para where the most important epidemics occurred in Belem. During the last two decades, ORO virus has spread to neighboring states of Amazonas, Amapa, Acre, Rondônia, Maranhão and Tocantins (Nunes et al., 2005).

Culicoides paraensis is the most widespread species in the New World. It occurs in the southeastern United States as far north as Pennsylvania and Wisconsin, and south through Central and South America to Uruguay (Salto) (Felipe-Bauer et al., 2003). Despite its widespread distribution in the states of the north, northeast and south of Brazil, this species is poorly collected and infestations were mainly reported in the northern states where it is associated with ORO in endemic sites. Only Sherlock (1963) previously mentioned *C. paraensis* as a pest in Salvador, Bahia, causing allergic dermatitis in the local residents.

METHODS

Between February and September 2002, representatives of the cities' governments of Jaragua do Sul, Corupa, Schroeder, Guaramirim and Massaranduba in the Itapocu River Valley (1723 km²) in northeast Santa Catarina (Fig.1), sent us samples of *Culicoides*, collected from schools, day-care centers, and residences where females were biting exposed parts of the body (legs, arms, face) of local residents. Some people developed eczema, mainly on the legs, due to allergic reactions caused by the bite of these insects. The collections were made in different day's hours due to the availability of the local agents at 91 rural, periurban, and urban

sites described in Table 1. Infested sites were signaled in Jaragua do Sul (533 km²) and Corupa (405 km²), the two cities with the biggest claims (Fig. 2). The species were identified based in the Atlas of *Culicoides* (Wirth et al., 1988) and in the key and diagnostic characters of *Culicoides* of the *paraensis* species group that can be found in Felipe-Bauer et al. (2003).

RESULTS

A total of 3,640 specimens of *Culicoides* were captured during this study: 1,254 from Jaragua do Sul, 1,344 from Corupa, 611 from Guaramirim, 363 from Schroeder and 68 from Massaranduba. Of these, 3,516 specimens were *C. paraensis* and 124 *C. insignis* Lutz. The latter species was found only in one collection made in a rural site from the city of Guaramirim near an irrigated rice plantation, whereas in all other sites only *C. paraensis* was captured. *Culicoides* adult populations in the cities of the Itapocu River Valley are therefore due nearly entirely to the high incidence of *C. paraensis*.

DISCUSSION

The economies of the cities of the Itapocu River Valley are based mainly on the intensive culture of banana (Musaceae) (Table 1). As observed in other areas with the same cultural practices, after felling of banana trees, the stems, stumps and other banana plant residues are left in the environment for decomposition. Several authors (e.g. Winder and Silva, 1972; Winder, 1977; Hoch et al., 1987; Mercer et al., 2003) have shown that *C. paraensis* emerge from decaying vegetation. The change of the forest environment to agricultural sites, like banana plantations, provides an increase in the incidence of this species due to the greater availability of breeding substrates.

In order to identify the preferred larval development sites of *C. paraensis* in areas of banana monoculture, studies have been started in Jaragua do Sul. This information may provide knowledge toward development of an alternative management regime of banana plantations. Changes to the cultivation methods of this important crop will likely contribute to future *Culicoides* control programs in the cities of the Itapocu River Valley.

In Brazil, the ORO virus was restricted to the areas with occurrence of ORO fever, especially those in the Amazon Basin. Recently, Nunes et al. (2005) isolated the genotype III of ORO virus from monkeys (*Callithrix*) in the Arinos region of the state of Minas Gerais, a genotype reported previously only in Panama.

The record of the ORO virus outside the states of the Amazon Basin, in sylvatic areas of southeastern Brazil and the report of established populations of *C. paraensis* in urban areas of Santa Catarina demands special attention. Unlike that in the Amazon region of Brazil, banana culture in southern Brazilian states is extensively cultivated in populous urban areas. The potential of transportation of this arbovirus from natural habitats to urban areas and the risk of spreading ORO fever to susceptible populated regions of southeastern and southern Brazil must be addressed by government health agencies. Clearly, additional studies regarding the bioecological aspects of the vector, as well as the spatial distribution of the ORO virus and its vectors are needed to better understand the potential risk of spreading this epidemic arboviral disease in Brazil.

ACKNOWLEDGEMENTS

We are grateful to the Associação dos Municípios do Vale do Rio Itapocu (AMVALI) and the city governments of Jaraguá do Sul, Corupa, Guarimir, Schroeder and Massaranduba for financial support. We thank Maria Teresa Nora Amorim for her prompt assistance, Arnaldo Kersten for his technical support with field collections, Enaly Silva Ribeiro and Lina Lane Ferreira for counting the specimens, Art Borkent and William Grogan for critical review of the manuscript, and to the many collectors and residents for their assistance.
