Chronic Chagas disease cardiomyopathy (CCC), caused by Trypanosoma cruzi infection, is an important cause of morbidity and mortality in endemic countries. It is estimated that approximately 7 million people are infected worldwide, with high prevalence in Latin America and growing incidence in developed countries because of globalization.1,2 It is estimated that the cardiac form of the disease occurs in approximately 20% to 30% of infected subjects.3 Antiparasitic drugs are effective during acute infection, but fail to improve established CCC.4 Besides standard heart failure treatment, patients with advanced CCC rely on heart transplantation, which is limited because of organ availability and complications relative to parasite reactivation after immunosuppression therapy.5

During CCC, cardiomyocytes are lost as a result of damage caused by immune responses directed to the parasites that persist in the heart, as well as to autoreactive cells directed to heart antigens.6,7 Although the mechanisms of pathogenesis are not completely understood, several studies indicate the involvement of type 1 helper T-cell lymphocytes associated with high production of interferon-γ (IFN-γ), resembling a delayed hypersensitivity reaction.6 An association between progression to severe chronic forms and a high production of IFN-γ was observed in...
patients with Chagas disease.\textsuperscript{8} Macrophages, a major cell population found in the inflammatory sites, can be activated by IFN-γ and tumor necrosis factor-α, two inflammatory cytokines overexpressed in the hearts of mice chronically infected with \textit{T. cruzi}. Furthermore, several genes related to the inflammatory response are up-regulated in heart tissue during the chronic phase of \textit{T. cruzi} infection.\textsuperscript{9}

Previous studies suggested that activated macrophages secrete galectin-3 (Gal-3), a molecule involved in the pathogenesis of cardiac dysfunction.\textsuperscript{10} Gal-3 is a soluble β-galactoside binding lectin involved in a variety of cellular processes, including proliferation, migration, and apoptosis.\textsuperscript{11} The importance of this protein in the regulation of cardiac fibrosis and remodeling has been highlighted by the demonstration of its contribution to the development and progression of heart failure in different experimental settings.\textsuperscript{12–14} Serum Gal-3 concentrations are also increased in patients with acute decompensated heart failure. On the basis of these findings, the value of Gal-3 as a prognostic biomarker in patients with chronic heart failure has been investigated.\textsuperscript{15}

Previously, we performed transcriptomic analysis in the cardiac tissue of mice chronically infected with \textit{T. cruzi}, and found that \textit{Lgals3}, the gene encoding for Gal-3, is among the most overexpressed genes.\textsuperscript{16} By immunofluorescence analysis, we showed that Gal-3 is mainly expressed in inflammatory cells in the hearts of \textit{T. cruzi}–infected mice. We hypothesized that Gal-3 plays a role in the pathogenesis of CCC, contributing to the progression of inflammation and fibrosis. In the present study, we evaluated the expression of Gal-3 during \textit{T. cruzi} infection in mice. Gal-3 expression was also investigated in human heart samples, to validate the expression of this protein in the human disease setting. Finally, we conducted \textit{in vitro} and \textit{in vivo} studies involving genetic and pharmacological blockades of Gal-3 to investigate its potential role in disease pathogenesis and its usefulness as a target for therapeutic development.

**Materials and Methods**

**Animal Procedures**

Six- to eight-week-old female C57BL/6 mice were used for \textit{T. cruzi} infection and as normal controls. Galectin-3 C57Bl/6 female mice were used in cell adhesion experiments. All animals were raised and maintained at the animal facility of the Center for Biotechnology and Cell Therapy, Hospital São Rafael, in rooms with controlled temperature (22°C ± 2°C) and humidity (55% ± 10%), and continuous air flow. Animals were housed in a 12-hour light/12-hour dark cycle (6AM to 6PM) and provided with standard rodent diet and water ad libitum. Animals were handled according to the NIH guidelines for animal experimentation.\textsuperscript{17} All procedures described had prior approval from the local institutional animal ethics committee at Hospital São Rafael (01/13).

**Trypanosoma cruzi Infection**

Trypomastigotes of the myotropic Colombian \textit{T. cruzi} strain were obtained from culture supernatants of infected LLC-MK2 cells, as previously described.\textsuperscript{9} Infection of C57BL/6 mice was performed by i.p. injection of 1000 \textit{T. cruzi} trypomastigotes in saline, and was confirmed through evaluation of parasitemia at different time points after infection.

**Pharmacological Blockade of Gal-3 with N-Lac**

C57Bl/6 female mice (\textit{n} = 11) chronically infected with \textit{T. cruzi} (6 months postinfection (m.p.i.)) were treated with N-acetyl-D-lactosamine (N-Lac) (Sigma-Aldrich, St. Louis, MO), 5 mg/kg per day, i.p. injections 3× per week, for 60 days. Chronically infected mice injected with saline (\textit{n} = 10) and same age naïve mice (\textit{n} = 8) served as controls. Functional analyses were performed, as described below. Mice were euthanized, by cervical dislocation under anesthesia with 5% ketamine (König, São Paulo, Brazil) and 2% xylazine (König Lab), the week after the final N-Lac injection. Heart samples were collected for real-time quantitative PCR and histological analysis. In another experiment, sucrose (Sigma-Aldrich) was administered in the same regimen as N-Lac to C57BL/6 mice, after 6 months of infection with \textit{T. cruzi}. Heart samples were collected for histological analysis.

**Functional Analysis**

Electrocardiography was performed using the Bio Amp PowerLab System (PowerLab 2/20; ADInstruments, Sydney, Australia), recording the bipolar lead I. All animals were anesthetized by i.p. injection of 10 mg/kg xylazine and 100 mg/kg ketamine to obtain the records. All data were acquired for computer analysis using Chart 5 for Windows (ADInstruments). The electrocardiographic analysis included heart rate, PR interval, P wave duration, QT interval, QTc, and arrhythmias. The QTc was calculated as the ratio of QT interval by square roots of RR interval.

A motor-driven treadmill chamber for one animal (LE 8700; Panlab, Barcelona, Spain) was used to exercise the animals. The speed of the treadmill and the intensity of the shock (mA) were controlled by a potentiometer (LE 8700; Panlab, Barcelona, Spain) was used to exercise the animals. After an adaptation period in the treadmill chamber, the mice exercised at five different velocities (7.2, 14.4, 21.6, 28.8, and 36.0 m/minute), with increasing velocity after 5 minutes of exercise at a given speed. Velocity was increased until the animal could no longer sustain a given speed and remained >5 seconds on an electrified stainless-steel grid. Total running distance was recorded.

**Morphometric Analysis**

Two months after the therapy, mice were euthanized as mentioned before and hearts were collected and fixed in 10% buffered formalin. Heart sections were analyzed by
light microscopy after paraffin embedding, followed by standard hematoxylin and eosin staining. Inflammatory cells infiltrating heart tissue were counted using a digital morphometric evaluation system. Images were digitized using the slide scanner ScanScope (Leica, Wetzlar, Germany). Morphometric analyses were performed using Image Pro Plus software version 7.0 (Media Cybernetics, Rockville, MD). The inflammatory cells were counted in 10 fields (×400 magnification) per heart sample. The percentage of fibrosis was determined using Sirius red—stained heart sections and the Image Pro Plus version 7.0. Two blinded investigators performed the analyses (J.F.V. and C.M.A.).

**Immunofluorescence Analysis**

Frozen (10 µm thick) or formalin-fixed, paraffin-embedded (3 µm thick) heart sections were obtained. Paraffin-embedded tissues were deparaffinized and submitted to a heat-induced antigen retrieval step by incubation in citrate buffer (pH = 6.0). Then, sections were incubated overnight at 4°C with the following primary antibodies: anti–Gal-3, diluted 1:400 (Santa Cruz Biotechnology, Dallas, TX) and anti-CD11b, diluted 1:400 (BD Biosciences, San Jose, CA). Next, the sections were incubated for 1 hour with secondary antibodies anti-goat IgG Alexa Fluor 488-conjugated and anti-rat IgG Alexa Fluor 594-conjugated (1:400; ThermoFisher Scientific, Waltham, MA). Immunostaining for in vitro experiments was performed in cardiac fibroblasts or bone marrow—derived macrophages plated on coverslips. The cells were fixed with paraformaldehyde 4% and incubated with the primary antibodies: goat anti–Gal-3, diluted 1:400 (Santa Cruz Biotechnology), or rabbit anti-collagen type I, diluted 1:50 (Novotec, Lyon, France). On the following day, sections were incubated for 1 hour with phalloidin conjugated with Alexa Fluor 633 or 488 conjugated, diluted 1:50, mixed with the secondary antibodies anti-goat IgG Alexa Fluor 488-conjugated (1:400) or anti-rabbit IgG Alexa Fluor 568-conjugated (1:200; all from ThermoFisher Scientific), respectively. Nuclei were stained with DAPI (VectorShield mounting medium with DAPI H-1200; Vector Laboratories, Burlingame, CA). The presence of fluorescent cells was determined by observation on a Fluoview 1000 confocal microscope (Olympus, Tokyo, Japan) and A1+ confocal microscope (Nikon, Tokyo, Japan). Quantifications of Gal-3+ cells were performed in 10 random fields captured under ×400 magnification, using the Image Pro Plus software version 7.0.

**Flow Cytometry Analysis**

Control and T. cruzi—infected mice were euthanized, hearts were collected, perfused with phosphate-buffered saline (PBS) to remove blood cells, and processed by enzymatic digestion using 0.1% collagenase IV (Sigma-Aldrich) and 10 µg/mL DNase (Roche, Basel, Switzerland), for 40 minutes, at 37°C. To evaluate the subpopulations of digested cardiac tissue samples, cell suspensions were allowed to pass through a 70-µm cell strainer (BD Biosciences) and counted. Aliquots of 10^6 cells were used for each test tube and 1 µL of Fc blocking reagent (BD Biosciences) was added. The fluorochrome-conjugated antibody panels used for each subpopulation were: i) T lymphocytes: CD45-APC-Cy7, CD3-APC, CD4-PE-Cy5, CD8-PE (BD Biosciences); ii) macrophages: CD45-APC-Cy7, CD11b-APC (eBioscience, San Diego, CA); iii) fibroblast/fibrocyte: CD45-APC-Cy7, vimentin-APC (Cell Signaling, Danvers, MA). Each antibody was diluted as suggested on the product data sheet. Samples were incubated for 20 minutes at room temperature in the dark. For intracellular staining of Gal-3, samples were washed once in PBS and CytoFix/CytoPerm kit (BD Biosciences) were used as directed on data sheet protocol. Anti–Gal-3–PE (R&D Systems, Minneapolis, MN) antibody was added to macrophages and fibroblast/fibrocyte sample tubes, whereas nonconjugated anti–Gal-3 (Santa Cruz Biotechnology) was added on T lymphocyte sample tube and its detection was performed by addition of anti-mouse IgG-Alexa Fluor 488 (ThermoFisher Scientific). Each incubation step was performed during 30 minutes at room temperature in the dark. Samples were washed twice and resuspended in PBS and added with HoechsT 33258 to exclude cell debris from analysis. Apoptosis was evaluated by annexin V-PI assay. Cells were harvested from culture flasks by adding TrypLE solution (ThermoFisher Scientific) and incubating for 5 minutes at 37°C. Cell suspensions were collected and washed with PBS by centrifugation at 300 × g. After discarding supernatant, pellets were resuspended in binding buffer (ThermoFisher Scientific) and cells were counted. Apoptosis assays were performed using annexin-V-APC and PI (BD Biosciences) according to the manufacturer’s recommendations. Sample acquisition was performed using a BD LSRFortessa SORP cytometer (BD Biosciences) using BD FacsDivata software version 6.2 (BD Biosciences). Ten thousand events were acquired per sample, and the data were analyzed using FlowJo software version 7.5 (FlowJo Enterprise, Ashland, OR).

**Real-Time RT-PCR**

Total RNA was isolated from heart samples with TRIzol reagent (ThermoFisher Scientific) and the concentration was determined by spectrophotometry. High Capacity cDNA Reverse Transcription Kit (ThermoFisher Scientific) was used to synthesize cDNA of 1 µg RNA following manufacturer’s recommendations. Real-time RT-PCR assays were performed to detect the expression levels of Tbet (Mm_00450960_m1), Gata3 (Mm_00484683_m1), Tnf (Mm_0043258_m1), Il10 (Mm_00439616_m1), Foxp3 (Mm_00475162_m1), Lgals3 (Mm_00829011_m1), and Mmp9 (Mm_0044299_m1). Other primer sequences used in real-time PCR analyses: Col1a1: 5'-GTCTCCCTCGACTTCTACACATCTTCTGA-3' (forward) and 5'-AAACCCGAGGTATGCTTGATCT-3' (reverse); Ccl2: 5'-TCCGCAAGCATGCACAGA-3'.
Design of shRNAs and Production of Lentiviral Vectors

To stably knock down Lgals3 expression, we designed shRNA against different regions of the Lgals3 coding sequence, and a scramble shRNA as control. Target sequences were designed using the online tool siRNA Wizard software version 3.1 (Invivogen, San Diego, CA). All suggested sequences were blasted against the mouse RNA database. The real-time RT-PCR amplifications consisted of a 20 ng template cDNA, TaqMan Master Mix (10 µL) and probes, constituting a final volume of 20 µL (all from ThermoFisher Scientific). All reactions were run in duplicate on an ABI7500 Sequence Detection System (ThermoFisher Scientific) under standard thermal cycling conditions. The mean Ct values from duplicate measurements were used to calculate expression of the target gene, while normalized to an internal control (Gapdh) using the 2-ΔCt formula. Experiments with CVs >5% were excluded. A nontemplate control and nonreverse transcription controls were also included.

In Vitro Studies with Cardiac Fibroblasts and Bone Marrow–Derived Macrophages

Cardiac fibroblasts were isolated from hearts of adult C57BL/6 mice, euthanized as described above. Hearts were minced into pieces of 1 mm and incubated with 0.1% collagenase type A (Sigma-Aldrich) at 37°C for 30 minutes, under constant stirring. The cell suspension was passed through a 70-µm cell strainer (BD Biosciences), and plastic-adherent cells were selected by 1 hour incubation in gelatin-coated flasks (Sigma-Aldrich). Nonadherent cells from supernatant were removed and adherent cells were cultured with Dulbecco’s modified Eagle’s medium supplemented with 10% fetal bovine serum and 1% penicillin and streptomycin (all from ThermoFisher Scientific), in a humidified incubator at 37°C with 5% CO₂. Culture medium was changed every 3 days, and cells were trypsinized (trypsin-EDTA 0.05%; ThermoFisher Scientific) when 80% confluence was reached. Cell cycle studies were performed with CFSE Cell Proliferation Kit (ThermoFisher Scientific), according to the manufacturer’s instructions. Proliferation of cardiac fibroblasts was assessed by the measurement of ³H-thymidine uptake. Cells were plated in 96-well plates, at a density of 10⁴ cells/well, in a final volume of 200 µL, in triplicate, and cultured in the absence or presence of 30 µg/mL rmGal-3 (R&D Systems), with or without 1% modified citrus pectin (ecoNugenics, Santa Rosa, CA). After 24 hours, plates were pulsed with 1 µCi of methyl-³H thymidine (PerkinElmer, Waltham, MA) for 18 hours, and proliferation was assessed by measurement of ³H-thymidine uptake by using a Chameleon β-plate counter (Hydex, Turku, Finland). Proliferation capacity of Gal-3 knockdown and control cell lines was compared by ³H-thymidine incorporation, using the same procedures.

To obtain macrophages, bone marrow cells were harvested from femurs of C57BL/6 mice by flushing with cold RPMI 1640 medium. Bone marrow cells were induced to differentiate into macrophages by culture in RPMI 1640 supplemented with 10% fetal bovine serum (ThermoFisher Scientific), 50 U/mL of penicillin, 50 µg/mL of streptomycin, 2.0 g/L of sodium bicarbonate, 25 mmol/L HEPES, 2 mmol/L
glutamine, and 30% supernatant obtained from X63-GM-CSF\textsuperscript{19} cell line culture, at 37°C and 5% CO\textsubscript{2}. Cells were cultured for 7 days, with half medium changes every 3 days. Differentiated macrophages were plated onto 24-well plates and incubated in medium alone or with 1 μg/mL lipopolysaccharide (Sigma-Aldrich) with or without 50 ng/mL IFN-γ (R&D Systems). After 24 hours, macrophages were detached using a cell scraper and analyzed for Gal-3 expression by flow cytometry, as described above.

**Human Samples**

The procedures involving human samples received prior approval by the local Ethics committee at Hospital São Rafael (approval number 51025115.3.0000.0048). Samples were obtained at Messejana Hospital in Fortaleza, Ceará, a medical center specialized for heart transplantation in Brazil. Fragments of explanted hearts from three patients with Chagas disease, confirmed by serological assay, were obtained from left ventricle and septum. Samples were processed in paraffin and stained with hematoxylin and eosin and Sirius Red, or used for immunostaining for detection of Gal-3, as described above.

**Lymphoproliferation Assay**

Splenocyte suspensions, obtained from C57Bl/6 mice, were prepared in Dulbecco’s modified Eagle’s medium supplemented with 10% fetal bovine serum and 50 μg/mL of gentamicin. Splenocytes were cultured in 96-well plates at 1 × 10\textsuperscript{6} cells/well, in triplicate, and lymphocyte proliferation was stimulated or not with concanavalin A (2 μg/mL; Sigma-Aldrich) or Dynabeads mouse T-activator CD3/CD28 (ThermoFisher Scientific), according to the manufacturer’s instructions. Cell proliferation was induced in the absence or presence of various concentrations of N-Lac (10, 1, and 0.1 μmol/L). After 48 hours of incubation, 1 μCi of \textsuperscript{3}H-thymidine was added to each well, and the plate was incubated for 18 hours. Plates were frozen at −70°C, then thawed and transferred to UniFilter-96 GF/B PEI coated plates (PerkinElmer) with the assistance of a cell harvester. After drying, 50 mL of scintillation cocktail was added in each well, sealed and plate read at liquid scintillation microplate counter. Dexamethasone (Sigma-Aldrich; 10 μmol/L) was used as positive control. Three independent experiments were performed.

**En Face Leukocyte Adhesion Assay**

The aorta from the thoracic region and spleens were removed from wild-type and galectin-3 knockout C57BL/6 mice. Fragments of approximately 1 mm\textsuperscript{2} were placed with the intimal side up in 96-well plates previously coated with Matrigel (Corning Inc., Corning, NY) for 30 minutes at 37°C. Endothelium was activated by incubation with 500 ng/mL lipopolysaccharide (Sigma), whereas the splenocyte suspension with 2 μg/mL concanavalin A (Sigma)
and 500 ng/mL lipopolysaccharide, during a period of 6 hours.

Activated splenocytes were incubated with 1 μmol/L Celltracker Fluorescent Probes (Life Technologies) in serum-free RPMI 1640 medium (Gibco) for 30 minutes and washed three times, before adhesion to the endothelium. Splenocytes (5 × 10^5/well) were plated and incubated with the aortic endothelium fragments for 30 minutes at 37°C in the presence or absence of 10 μmol/L N-Lac (Sigma-Aldrich). Plates were then carefully washed three times with warm Hanks’ balanced salt solution to remove the nonadherent cells. Three replicates were used for each treatment. Different random areas per well were acquired using a digital camera from an inverted fluorescence microscope. Fluorescent cells were quantified using ImagePro.

Inhibition of Cell Migration Assay

C57BL/6 mice, 8 to 12 weeks old, were submitted to euthanasia by cervical dislocation under anesthesia. Spleens were collected, minced, cells were resuspended in PBS and passed through a 70-μm cell strainer. The cells were resuspended and maintained in RPMI 1640 medium (ThermoFisher Scientific), without serum, supplemented with 2 mmol/L L-glutamine (ThermoFisher Scientific), 0.1% RPMI 1640 vitamin solution (Sigma Aldrich), 1 mmol/L sodium pyruvate, 10 mmol/L HEPES, 50 μmol/L 2-mercaptoethanol, and penicillin/streptomycin solution (all from ThermoFisher Scientific). Splenocytes were incubated in starvation during 24 hours at 37°C and 5% CO₂, in the presence or absence of 10 μmol/L N-Lac. Migration assay was performed using the QCM Chemotaxis Cell Migration Assay, 24-well 3-μm pore (Millipore), according to the manufacturer’s instructions. Briefly, splenocytes were counted and 10⁷ cells in 250 μL were placed in the upper chamber, in serum-free medium, in the presence or absence of N-Lac. RPMI 1640 medium supplemented with 10% fetal bovine serum (ThermoFisher Scientific) with or without 10 μmol/L N-Lac was placed in the bottom chamber. Cells present in the bottom chamber were counted after overnight incubation.

Figure 2  Gal-3 is increased in different cell types involved in inflammation and tissue repair. Histograms showing flow cytometry analysis from digested heart tissue, obtained from naïve and infected mice, at 3 and 15 months postinfection (m.p.i.). Gal-3⁺ T CD4⁺ and CD8⁺ lymphocytes expressing Gal-3 are increased at 3 and 15 m.p.i. when compared to naïve controls. Most macrophages (CD45⁺/CD11b⁺), fibroblasts (CD45⁺/vimentin⁺), and bone marrow-derived fibrocytes (CD45⁺/vimentin⁺) express Gal-3 (>90%) in all groups, but the mean fluorescence intensity increases with time of infection.
Statistical Analysis

All continuous variables are presented as means ± SEM. Continuous variables were tested for normal distribution using Kolmogorov-Smirnov test. Parametric data were analyzed using unpaired t tests, for comparisons between two groups, and one-way analysis of variance, followed by Bonferroni post hoc test for multiple-comparison test, using Prism 6.0 (GraphPad, La Jolla, CA). \( P < 0.05 \) was considered statistically significant.

Results

Gal-3 Expression Is Increased during Experimental T. cruzi Infection

We first analyzed the expression of Gal-3 in mouse heart sections obtained at different time points of infection. Trypanosoma cruzi infection led to increased expression of Gal-3\(^+\) cells in the myocardium compared to naïve controls, as shown by confocal microscopy (Figure 1A–C). Quantification of Gal-3 expression showed a significant increase in all time points analyzed, in comparison with uninfected controls (Figure 1D). The number of Gal-3\(^+\) cells was higher at the peak of parasitemia (1 m.p.i.), when an intense acute inflammatory response is found in the heart (Figure 1E). The numbers of Gal-3\(^+\) cells during the chronic phase were sustained, whereas the percentage of fibrosis increased with time (Figure 1F). The population of Gal-3\(^+\) cells in the heart included macrophages (CD11b\(^+\) cells) (Figure 1G) and cardiac fibroblasts (Figure 1H). To investigate the role of proinflammatory signals in the expression of Gal-3 by macrophages, we performed \emph{in vitro} studies to analyze the expression of Gal-3 in activated macrophages. Bone marrow–derived macrophages activated with IFN-\(\gamma\) and Toll-like receptor 4 ligand lipopolysaccharide had an increased expression of Gal-3, as demonstrated by flow cytometry analysis (Figure 1I).

To better characterize the cell populations expressing Gal-3, we performed flow cytometry analysis of cells isolated from hearts of \textit{T. cruzi}–infected mice (Figure 2). Both CD4\(^+\) and CD8\(^+\) T cells had increased Gal-3 expression at 3 and 15 m.p.i. when compared to uninfected controls. In addition, macrophages, characterized as CD45\(^+/\)CD11b\(^+\), composed the cell populations expressing the higher mean fluorescence intensity of Gal-3 (Figure 2). Gal-3 was expressed at low levels in fibroblasts (vimentin\(^+/\)CD45\(^-\)) in control hearts, and was increased by 52.5\% at 3 m.p.i. Gal-3 expression intensity in fibroblasts at 15 m.p.i. returned to levels similar to those found in controls. However, a significant increase in Gal-3 expression was detected in a population of vimentin\(^+/\)CD45\(^-\) cells, characterized as bone marrow–derived fibrocytes, at 3 and 15 m.p.i., when compared to controls (Figure 2).

Expression of Gal-3 in the Hearts of Subjects with CCC

To evaluate if the presence of Gal-3\(^+\) cells in the myocardium of infected mice could be translatable to the human disease, we performed analysis in human heart samples obtained from explants of subjects with chronic Chagas cardiomyopathy who underwent heart transplantation. Heart sections were stained with hematoxylin and eosin, showing inflammatory infiltrates composed of mononuclear cells surrounding myofibers (A) and in areas of myocytolysis (B). Heart sections stained with Sirius red showing areas of mild (C) and extensive (D) cardiac fibrosis. E and F: Confocal microscopy analysis from two different subjects, showing Gal-3\(^+\) cells (red) in areas of inflammatory infiltrates. Nuclei are stained with DAPI (blue). Scale bars = 50 \(\mu\text{m}\) (A–C, E, and F); 25 \(\mu\text{m}\) (D).

Figure 3 Gal-3 expression in heart samples from subjects with end-stage Chagas cardiomyopathy. Representative images obtained from explanted heart sections of two subjects with end-stage Chagas cardiomyopathy who underwent heart transplantation. Heart sections were stained with hematoxylin and eosin, showing inflammatory infiltrates composed of mononuclear cells surrounding myofibers (A) and in areas of myocytolysis (B). Heart sections stained with Sirius red showing areas of mild (C) and extensive (D) cardiac fibrosis. E and F: Confocal microscopy analysis from two different subjects, showing Gal-3\(^+\) cells (red) in areas of inflammatory infiltrates. Nuclei are stained with DAPI (blue). Scale bars = 50 \(\mu\text{m}\) (A–C, E, and F); 25 \(\mu\text{m}\) (D).

Gal-3 Is a Major Regulator of Fibroblast Function

On the basis of the findings of increased Gal-3 expression in fibroblasts during the development of CCC, we performed \emph{in vitro} studies aiming at investigating the role of Gal-3 on different aspects of the biology of these cells. Cardiac
fibroblasts isolated from mouse hearts were incubated with mouse recombinant Gal-3 to evaluate their proliferative rate. We found that exogenous recombinant Gal-3, at a micromolar concentration, increased the proliferation of cardiac fibroblasts, whereas addition of modified citrus pectin, a Gal-3 binding partner, blocked the effect of Gal-3 (Figure 4A).

Considering that this effect was observed at high concentrations of exogenous Gal-3, and given the high expression of intracellular Gal-3 in cardiac fibroblasts in experimental CCC, we evaluated the role of endogenous Gal-3 in cardiac fibroblasts. We generated lentiviral vectors encoding shRNA targeting the Lgals3, together with green fluorescence protein expression as a reporter gene. Then, cardiac fibroblasts were transduced by lentiviral infection, resulting in the knockdown of Gal-3. The efficiencies of lentiviral infection and knockdown were confirmed by green fluorescence protein reporter gene expression and by quantification of Gal-3 gene and protein expressions by real-time quantitative PCR and immunofluorescence analysis, respectively (>90%) (Supplemental Figure S1, A–E). More important, Gal-3 knockdown in cardiac fibroblasts led to a down-regulation of type I collagen expression (Supplemental Figure S1, F–H).

Gal-3 knockdown was associated with a significant reduction in the proliferative rate of cardiac fibroblasts (Figure 4B). This finding was accompanied by a reduction of cyclin D1 gene expression (Figure 4C). Analysis of caveolin-1 gene expression did not show alterations when control or Gal-3 knockdown cells were compared (data not shown). Flow cytometry analysis showed cell cycle arrest in Gal-3 knockdown when compared to control cells (increased percentage of G0/G1 and decreased S and G2/M phases) (Figure 4, D–F).

To determine whether Gal-3 knockdown also affects cell survival, we evaluated the frequency of apoptosis in the culture of cardiac fibroblasts, by annexin V/PI staining and flow cytometry analysis. A higher percentage of apoptotic cells was detected in cultures of cardiac fibroblasts with Gal-3 knockdown when compared to controls (Figure 4G).

Treatment with the Gal-3 Blocking Agent N-Lac Reduces Inflammation and Fibrosis in Experimental CCC

To study the role of Gal-3 on the pathogenesis of CCC, we performed a pharmacological blockade of Gal-3 using N-Lac (Figure 5A), during the chronic phase of the infection, when cardiac fibrosis is significantly increased (6 and 8 m.p.i.). We performed functional evaluations (electrocardiographic analysis and treadmill test) before treatment (6 m.p.i.) and after the treatment with N-Lac (8 m.p.i.). Trypanosoma cruzi infection caused the development of arrhythmias and cardiac conduction disturbances, such as atrioventricular block, ventricular tachycardia, and ventricular bigeminy. Treatment with N-Lac did not alter the frequencies or the severity of arrhythmias when compared to those found in saline-treated controls (Table 1). Regarding
the exercise capacity, *T. cruzi*-infected mice had an impaired performance when compared to uninfected controls 6 months after infection (data not shown). N-Lac treatment did not cause any improvement in exercise capacity, because mice treated with this Gal-3 blocker had similar performance in treadmill test to saline-treated mice and a reduced capacity when compared to uninfected controls (Figure 5B).

Histological analysis demonstrated the presence of inflammatory infiltrate in the hearts of mice infected with *T. cruzi*, mainly composed of mononuclear cells. The number of inflammatory cells infiltrating the heart, however, was significantly reduced in N-Lac–treated mice, compared to saline-treated controls (Figure 5, C and D). In addition, the percentage of heart fibrosis was significantly reduced after N-Lac treatment when compared to saline-treated mice (Figure 5, C and E). In addition, a control experiment was performed in which *T. cruzi*-infected mice were treated in the same regimen with sucrose. Morphometric analysis in the hearts of sucrose-treated mice did not show reduction of inflammatory cells and the fibrotic area in sucrose-treated mice when compared to those treated with saline (Supplemental Figure S2).

To investigate whether N-Lac caused modulation of inflammatory mediators, we performed gene expression analysis in the heart tissue (Figure 6). N-Lac–treated mice had reduced gene expression of the inflammatory cytokines tumor necrosis factor-α and IFN-γ when compared to saline-treated mice. The regulatory cytokine IL-10 was increased in *T. cruzi*-infected mice when compared to uninfected controls, both in saline as well as in N-Lac–treated mice. Moreover, the gene expression of transcription factors T-bet, GATA-3, and FoxP3, associated with T-cell subtypes type 1 helper T cell, type 2 helper T cell, and T regulatory cell, respectively, was increased by *T. cruzi* infection and reduced in mice treated with N-Lac. The gene
expression of chemokine ligand 8 (modified citrus pectin 2) and the chemokine receptor CCR5, which are increased by T. cruzi infection, was also reduced after N-Lac treatment. More important, treatment with N-Lac reduced the gene expression of Gal-3 in the hearts of T. cruzi infected mice (Figure 6).

To better investigate the mechanisms by which N-Lac caused reduction of inflammation, we performed lymphoproliferation and migration assays. Mouse splenocytes were stimulated in vitro with concanavalin A or anti-CD3/CD28.

Addition of N-Lac at the highest concentration tested (10 μmol/L) caused a small reduction of lymphoproliferation stimulated by both polyclonal activators (Figure 7, A and B). In contrast, the positive control dexamethasone inhibited the proliferation induced by both stimuli. Last, we tested the effects of N-Lac in adhesion of leukocytes to the endothelium and in cell migration. The adhesion of leukocytes to aorta endothelium in an en face assay was significantly blocked by N-Lac using cells and endothelium from wild-type mice, but not from galectin-3 knockout mice (Figure 7C). In fact, cell adhesion of galectin-3 knockout mice was similar to that of pharmacological blockade with N-Lac in wild-type cells (Figure 7C), In addition, the presence of N-Lac significantly inhibited leukocyte migration in a transwell system (Figure 7D).

**Discussion**

Gal-3 is a multifunctional lectin that can be found in various cells and tissues, and is detected in the nucleus, cytoplasm, as well as in the extracellular compartment. Notably, Gal-3 may have different, concordant, or opposite actions depending on the cell type and whether it is present in the extracellular or intracellular compartments. Previous studies from our group and others have shown a correlation between inflammation and fibrosis in the heart and Gal-3 expression. Moreover, host expression of Gal-3 is required for T. cruzi adhesion and invasion in human cells.

In the present study, we demonstrated the expression of Gal-3 in different cell populations and its role in the promotion

| Table 1 ECG Analysis in Uninfected and Trypanosoma cruzi—Infected Mice |
|--------------------------|------------------|----------------|------------------|------------------|
| ECG findings             | Uninfected (n = 7) | Pretreatment (n = 19) | Saline (n = 9) | N-Lac (n = 10) |

Notably, Gal-3 may have different, concordant, or opposite actions depending on the cell type and whether it is present in the extracellular or intracellular compartments. Previous studies from our group and others have shown a correlation between inflammation and fibrosis in the heart and Gal-3 expression. Moreover, host expression of Gal-3 is required for T. cruzi adhesion and invasion in human cells.

In the present study, we demonstrated the expression of Gal-3 in different cell populations and its role in the promotion

**Figure 6** Modulation of gene expression in chagasic heart after N-Lac treatment, real-time RT-PCR analysis of gene expression in the heart tissue demonstrates that N-Lac treatment is associated with a reduction of inflammatory cytokines tumor necrosis factor (TNF)-α (A) and interferon (IFN)-γ (B), and does not alter the expression of IL-10 (C), when compared to saline-treated mice. T-lymphocyte subtype-specific transcription factors associated with type 1 helper T cell (T-bet; D), type 2 helper T cell (GATA-3; E), and T regulatory cell (FOXP3; F) are reduced in N-Lac–treated mice. The expression of genes associated with leukocyte migration and chemo-taxis CCR5 (G), chemokine ligand 8 (H), and Gal-3 (I) is also reduced after N-Lac treatment. Data are expressed as means ± SEM. *P < 0.05, **P < 0.01, and ***P < 0.001.
of heart inflammation and fibrosis in *T. cruzi*-infected mice. This was achieved by the following: i) immunostaining in chronic Chagas disease human and mouse heart samples showing the presence of Gal-3+ cells, including macrophages, T cells, fibroblasts, and fibrocytes; ii) blockade of Gal-3 expression in cardiac fibroblasts, showing its role on proliferation and collagen production; and iii) pharmacological blockade in vitro in the experimental model, showing significant reduction of inflammation, fibrosis, and production of key inflammatory mediators in the heart.

Previous studies have highlighted a role for Gal-3 in the cardiac remodeling process in different experimental settings, including experimental models of hypertrophic cardiomyopathy and myocardial infarction. These reports have focused on Gal-3 effects in cardiac fibroblasts, contributing to cell survival, proliferation, and extracellular matrix synthesis. In CCC, however, a massive infiltration of immune cells is observed in the heart, which leads to persistent immune-mediated myocyte damage, ultimately triggering a progressive fibrogenic response.

In the present study, we demonstrated the dynamic expression of Gal-3 in different periods during *T. cruzi* experimental infection and correlated with the findings of human heart analysis, in sections obtained from hearts of subjects with end-stage heart failure due to CCC. Gal-3 expression was observed in a similar pattern in human and mouse heart samples, mainly in areas of inflammatory infiltrates. Gal-3 has been previously described in immune cells and to participate in different aspects of innate and adaptive immune responses. In the experimental model, we showed expression of Gal-3 in macrophages and T cells, two main cell types present in the inflammatory foci in Chagas disease hearts. Moreover, we demonstrated that inflammatory stimuli increase the expression of Gal-3 in macrophages in vitro. Because IFN-γ and tumor necrosis factor-α are produced in mouse hearts chronically infected with *T. cruzi*, their action may account for the increased Gal-3 expression in macrophages. The described roles for Gal-3 in T-cell biology include the promotion of cell survival, proliferation, T-cell receptor signaling, and migration. In our study, we observed reduction of cell adhesion to endothelium and migration, but not of lymphocyte proliferation, by the Gal-3 inhibitor N-Lac, suggesting that the reduction of inflammation in the hearts of infected mice after N-Lac treatment is mainly because of reduction of cell migration.

In our study, we found that *T. cruzi* infection also increased the expression of Gal-3 in cardiac fibroblasts and, even more intensely, in a population of bone marrow-derived fibrocytes. Although cardiac fibroblasts have been classically described as the most important cell type involved in cardiac fibrosis, different studies have shown that bone marrow—derived fibrocytes play relevant roles in fibrogenesis and remodeling. Our data provided from in vitro assays in cardiac fibroblasts demonstrated the role of exogenous and endogenous Gal-3 in cell survival, proliferation, and type I collagen synthesis, which is supported by the current literature. The fact that extracellular Gal-3 increased cell proliferation only in high concentration and the marked reduction of proliferation in Gal-3 knockout cells indicate that intracellular Gal-3 has a critical role in cell proliferation regulation. Interestingly, Gal-3 has been...
previously shown to enhance cyclin D1 promoter activity, correlating with the cell cycle arrest and decreased expression of cyclin D1 gene in Gal-3 knockdown fibroblasts found in our study. The fact that caveolin-1 gene expression was not increased in Gal-3 knockdown cells reinforces a direct action of Gal-3 in the regulation of cyclin D1 gene transcription.

We have previously shown that Lgals3 gene expression is up-regulated in the hearts of mice during chronic T. cruzi infection. The correlation between intensity of myocarditis and presence of collagen type I, Gal-3, and α-smooth muscle actin—positive cells was also seen in a mouse model of T. cruzi infection. Gal-3 was implicated in the process of T. cruzi invasion. Altogether, these data suggest that Gal-3 is involved in different aspects of the pathogenesis of CCC, from T. cruzi infection to immune response, inflammation, and tissue repair. Interestingly, a reduction of Gal-3 expression in the heart was observed accompanying decreased fibrosis and myocarditis after granulocyte colony-stimulating factor treatment or cell therapy in chronically infected mice. In the present study, we showed that the Gal-3 pharmacological blockade with N-Lac significantly modulated the immune response in the hearts from CCC mice, reducing migration of immune cells to the myocardium and decreasing the expression of inflammatory type 1 helper T-cell cytokines and markers of type 2 helper T-cell and T regulatory cell lymphocyte subtypes, to the level of naïve control mice. Notably, the anti-inflammatory cytokine IL-10 was increased when compared to naïve mice. This finding, together with the observed reduced levels of IFNG and TNFA gene expression, demonstrates a potent anti-inflammatory effect of N-Lac. Moreover, N-Lac treatment was associated with a significant reduction of myocardial fibrosis, which is in accordance with a previous report in a different experimental model. Despite the reduction of inflammation and fibrosis, our results did not correlate with any improvement in functional parameters after N-Lac treatment. This finding does not exclude the possibility of long-term beneficial effects of Gal-3 blockade, nor that N-Lac treatment, at an earlier stage of the infection, which may prevent the deterioration of cardiac function.

The strong binding affinity between galectin-3 and N-acetyl-D-lactosamine has been previously reported. Moreover, in previous studies, similar dose and administration regimen of N-acetyl-D-lactosamine were used to block galectin-3 in mouse models of viral myocarditis and hypertensive cardiac remodeling. The reduction of inflammation and fibrosis observed after N-Lac treatment were not observed in mice treated with sucrose in the same dose and regimen. Moreover, pharmacological (by N-Lac) and genetic (gene knockout) blockade of Gal-3 had similar effects in cell adhesion to endothelium, and indicate that N-Lac does not interfere with selectin binding.

In a translational perspective, Gal-3 could be used in the clinical setting as either a novel biomarker or a therapeutic target. Although the identification of novel noninvasive biomarkers that adequately predict cardiac fibrosis would be highly desired, in a recent report we showed that plasma Gal-3 levels do not correlate with the intensity of fibrosis, as measured by magnetic resonance imaging, in a recently published transversal study in subjects with CCC. Nonetheless, these data do not exclude the possibility of Gal-3 being useful as a biomarker for prognosis determination, which is currently under investigation in chronic heart failure caused by other etiologies. Thus, the conduction of a longitudinal study in Chagas disease subjects would be required to validate the use of plasma Gal-3 as prognosis biomarker.

In conclusion, herein, we demonstrated that Gal-3 plays an important role in the pathogenesis of experimental chronic Chagas disease, acting in different cell compartments and promoting cardiac inflammation and fibrosis. The finding of Gal-3 expression in human heart samples, in a similar pattern as observed in the mouse model, reinforces its potential as a novel target for drug and therapy development for CCC.

Acknowledgments

We thank Pamela Daltro for technical assistance in the cardiac functional analysis, Didier Trono for providing galectin-3 lentiviral vector, Dr. Luiz R. Goulart for providing galectin-3 knockout mice, and Drs. Igor Correia de Almeida and Washington Luis Conrado dos Santos for helpful discussions.
